Feature selection

PREPROCESSING FOR MACHINE LEARNING IN PYTHON

What is feature selection?

- Selecting features to be used for modeling
- Doesn't create new features
- Improve model's performance

When to select features

city	state	lat	long
hico	tx	31.982778	-98.033333
mackinaw city	mi	45.783889	-84.727778
winchester	ky	37.990000	-84.179722

- Reducing noice
- Features are strongly statistically correlated
- Reduce overall variance

Removing redundant features

PREPROCESSING FOR MACHINE LEARNING IN PYTHON

Redundant features

- Remove noisy features
- Remove correlated features
- Remove duplicated features

Scenarios for manual removal

city	state	lat	long
hico	tx	31.982778	-98.033333
mackinaw city	mi	45.783889	-84.727778
winchester	ky	37.990000	-84.179722

Correlated features

- Statistically correlated: features move together directionally
- Linear models assume feature independence
- Pearson's correlation coefficient

Correlated features

```
print(df)
```

```
A B C
0 3.06 3.92 1.04
1 2.76 3.40 1.05
2 3.24 3.17 1.03
...
```

```
print(df.corr())
```

```
A B C
A 1.000000 0.787194 0.543479
B 0.787194 1.000000 0.565468
C 0.543479 0.565468 1.000000
```

Selecting features using text vectors

PREPROCESSING FOR MACHINE LEARNING IN PYTHON

Looking at word weights

```
print(tfidf_vec.vocabulary_)
```

```
{'200': 0,
  '204th': 1,
  '33rd': 2,
  'ahead': 3,
  'alley': 4,
  ...
```

```
print(text_tfidf[3].data)

[0.19392702 0.20261085 ...]

print(text_tfidf[3].indices)

[ 31 102 20 70 5 ...]
```

Looking at word weights

```
vocab = {v:k for k,v in
tfidf_vec.vocabulary_.items()}
print(vocab)
```

```
{0: '200',
  1: '204th',
  2: '33rd',
  3: 'ahead',
  4: 'alley',
  ...
```

```
{5: 0.1597882543332701,
7: 0.26576432098763175,
8: 0.18599931331925676,
9: 0.26576432098763175,
10: 0.13077355258450366,
...
```

Looking at word weights

```
def return_weights(vocab, vector, vector_index):
   zipped = dict(zip(vector[vector_index].indices,
                      vector[vector_index].data))
   return {vocab[i]:zipped[i] for i in vector[vector_index].indices}
print(return_weights(vocab, text_tfidf, 3))
{'and': 0.1597882543332701,
 'are': 0.26576432098763175,
 'at': 0.18599931331925676,
```

Dimensionality reduction

PREPROCESSING FOR MACHINE LEARNING IN PYTHON

Dimensionality reduction and PCA

- Unsupervised learning method
- Combines/decomposes a feature space
- Feature extraction here we'll use to reduce our feature space

- Principal component analysis
- Linear transformation to uncorrelated space
- Captures as much variance as possible in each component

PCA in scikit-learn

```
from sklearn.decomposition import PCA
pca = PCA()
df_pca = pca.fit_transform(df)
print(df_pca)
[88.4583, 18.7764, -2.2379, \ldots, 0.0954, 0.0361, -0.0034],
[93.4564, 18.6709, -1.7887, ..., -0.0509, 0.1331, 0.0119],
[-186.9433, -0.2133, -5.6307, \ldots, 0.0332, 0.0271, 0.0055]
print(pca.explained_variance_ratio_)
[0.9981, 0.0017, 0.0001, 0.0001, ...]
```

PCA caveats

- Difficult to interpret components
- End of preprocessing journey
