Regression review

EXTREME GRADIENT BOOSTING WITH XGBOOST

Sergey Fogelson

Head of Data Science, TelevisaUnivision

Regression basics

• Outcome is real-valued

Common regression metrics

- Root mean squared error (RMSE)
- Mean absolute error (MAE)

Computing RMSE

Actual	Predicted
10	20
3	8
6	1

Computing RMSE

Actual	Predicted	Error
10	20	-10
3	8	-5
6	1	5

Computing RMSE

Actual	Predicted	Error	Squared Error
10	20	-10	100
3	8	-5	25
6	1	5	25

- Total Squared Error: 150
- Mean Squared Error: 50
- Root Mean Squared Error: 7.07

Computing MAE

Actual	Predicted	Error
10	20	-10
3	8	-5
6	1	5

• Total Absolute Error: 20

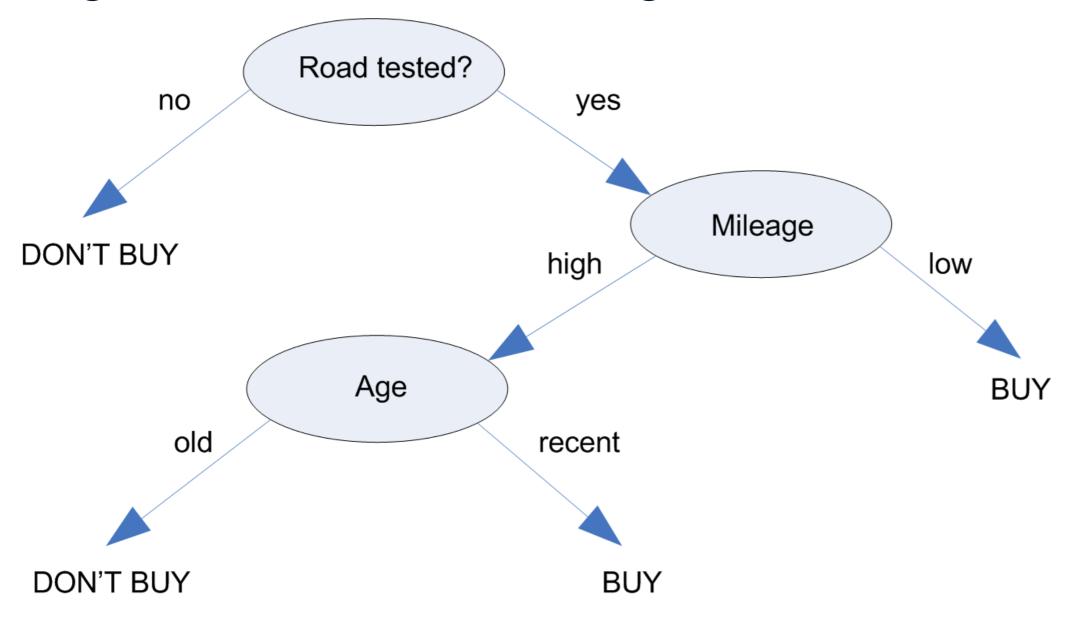

Mean Absolute Error: 6.67

Common regression algorithms

- Linear regression
- Decision trees

Algorithms for both regression and classification

Let's practice!

EXTREME GRADIENT BOOSTING WITH XGBOOST

Objective (loss) functions and base learners

EXTREME GRADIENT BOOSTING WITH XGBOOST

Sergey FogelsonHead of Data Science, TelevisaUnivision

Objective Functions and Why We Use Them

- Quantifies how far off a prediction is from the actual result
- Measures the difference between estimated and true values for some collection of data
- Goal: Find the model that yields the minimum value of the loss function

Common loss functions and XGBoost

- Loss function names in xgboost:
 - reg:linear use for regression problems
 - reg:logistic use for classification problems when you want just decision, not probability
 - binary:logistic use when you want probability rather than just decision

Base learners and why we need them

- XGBoost involves creating a meta-model that is composed of many individual models that combine to give a final prediction
- Individual models = base learners
- Want base learners that when combined create final prediction that is non-linear
- Each base learner should be good at distinguishing or predicting different parts of the dataset
- Two kinds of base learners: tree and linear

Trees as base learners example: Scikit-learn API

```
import xgboost as xgb
import pandas as pd
import numpy as np
from sklearn.model_selection import train_test_split
boston_data = pd.read_csv("boston_housing.csv")
X, y = boston_data.iloc[:,:-1],boston_data.iloc[:,-1]
X_train, X_test, y_train, y_test= train_test_split(X, y, test_size=0.2,
                                                         random state=123)
xg_reg = xgb.XGBRegressor(objective='reg:linear', n_estimators=10,
                                                   seed=123)
xg_reg.fit(X_train, y_train)
preds = xg_reg.predict(X_test)
```

Trees as base learners example: Scikit-learn API

```
rmse = np.sqrt(mean_squared_error(y_test,preds))
print("RMSE: %f" % (rmse))
```

RMSE: 129043.2314

Linear base learners example: learning API only

```
import xgboost as xgb
import pandas as pd
import numpy as np
from sklearn.model_selection import train_test_split
boston_data = pd.read_csv("boston_housing.csv")
X, y = boston_data.iloc[:,:-1],boston_data.iloc[:,-1]
X_train, X_test, y_train, y_test= train_test_split(X, y, test_size=0.2,
                                                          random state=123)
DM_train = xqb.DMatrix(data=X_train,label=y_train)
DM_test = xqb.DMatrix(data=X_test,label=y_test)
params = {"booster":"qblinear", "objective": "req:linear"}
xq_req = xqb.train(params = params, dtrain=DM_train, num_boost_round=10)
preds = xg_reg.predict(DM_test)
```

Linear base learners example: learning API only

```
rmse = np.sqrt(mean_squared_error(y_test,preds))
print("RMSE: %f" % (rmse))
```

RMSE: 124326.24465

Let's get to work!

EXTREME GRADIENT BOOSTING WITH XGBOOST

Regularization and base learners in XGBoost

EXTREME GRADIENT BOOSTING WITH XGBOOST

Sergey FogelsonHead of Data Science, TelevisaUnivision

Regularization in XGBoost

- Regularization is a control on model complexity
- Want models that are both accurate and as simple as possible
- Regularization parameters in XGBoost:
 - gamma minimum loss reduction allowed for a split to occur
 - alpha I1 regularization on leaf weights, larger values mean more regularization
 - lambda I2 regularization on leaf weights

L1 regularization in XGBoost example

Base learners in XGBoost

- Linear Base Learner:
 - Sum of linear terms
 - Boosted model is weighted sum of linear models (thus is itself linear)
 - Rarely used
- Tree Base Learner:
 - Decision tree
 - Boosted model is weighted sum of decision trees (nonlinear)
 - Almost exclusively used in XGBoost

Creating DataFrames from multiple equal-length lists

```
pd.DataFrame(list(zip(list1,list2)),columns=
["list1","list2"]))
```

- zip creates a generator of parallel values:
 - \circ zip([1,2,3],["a","b""c"]) = [1,"a"],[2,"b"],[3,"c"]
 - generators need to be completely instantiated before they can be used in DataFrame objects
- list() instantiates the full generator and passing that into the DataFrame converts the whole expression

Let's practice!
